Abstract
An 86-year-old man presented with benign essential blepharospasm with apraxia of eyelid opening unresponsive to botulinum toxin type A treatment. He was successfully treated with bilateral frontalis suspension with upper blepharoplasty. Postoperatively, he was able to open his eyes without difficulty and resume his daily activities.

Introduction
Benign essential blepharospasm (BEB) is characterized by repeated, involuntary, and intermittent forceful closure of eyelids without any ocular irritation. BEB can usually be controlled by repeat injections of botulinum toxin type A. Among patients with BEB, 7% have associated apraxia of eyelid opening (AEO). Rarely, some patients have pure AEO and were unresponsive to botulinum toxin therapy.1,2 Surgical treatments such as blepharoplasty, limited myectomy, aponeurosis repair, and frontalis suspension operation can be considered.3 We report on a patient who had refractory BEB with AEO and dermatochalasis and was successfully treated with frontalis suspension and blepharoplasty.

Case presentation
In September 2015, an 86-year-old man presented with a 3-year history of difficulty in opening his eyes with involuntary eyelids closure. His eyes were closed for most of the time and could only be opened mechanically by fingers. His daily activities were greatly affected. The patient had undergone bilateral cataract surgeries. He had medically controlled glaucoma, hypertension (with Norvasc), dementia (with Exelon), iron deficiency anemia (with iron supplements) and hearing impairment (with hearing aids).

On examination, his eyes were forcefully closed with bilateral dermatochalasis (Figure a). His cornea, tear film, and eyelid margins were unremarkable. His intraocular pressure was within normal limits, and fundi were unremarkable. The patient was not able to follow instructions for examinations owing to dementia and eyelid spasm. Therefore, the levator function and marginal reflex distance could not be properly measured. He was initially diagnosed with BEB and was treated with repeat injections of botulinum toxin type A (17.5 units per eye per session). The botulinum toxin was injected at seven points into the orbital parts and palpebral parts (preseptal / pretarsal regions) of orbicularis oculi (four points in the upper eyelid laterally and medially, two points in the lower eyelid laterally and medially, and one at the lateral canthus). However, 3 months later, the patient still could not open his eyes. AEO was suspected, and he was referred to the oculoplastic clinic for surgical management. Frontalis suspension and upper eyelid blepharoplasty were discussed. Surgeries were performed at the left side first and then the right side. About 12 mm of skin was excised on both sides. A silicone rod was sutured directly to the tarsal plate with 6-O dermalon, and it was retrieved onto the forehead using Fascia Wright needle. Skin wounds were closed with 6-O vicryl and silk.

Postoperatively, the ptosis and dermatochalasis were corrected without any complications (Figure b). The patient

had no lagophthalmos nor dry eyes symptoms. He was able
to rapidly open his eyes and resume normal daily activities.
Two more botulinum toxin treatments were given to improve
blepharospasm. He was satisfied with the improvement and
decided further botulinum toxin treatment.

Discussion

Frontalis suspension is a minimally invasive surgical
option for blepharospasm and AEO (the latter is known to
unresponsive to botulinum toxin treatment).2-7 The traction of
the frontalis muscles is directed to the upper eyelids by non-
elastic materials (eg, silicone rod, Gore-Tex thread).3
Frontalis suspension has good long-term effects and is well-accepted
by patients.5,7 Most patients receive continued botulinum
therapy to alleviate the orbicularis oculi contraction.5
Frontalis suspension with concomitant upper blepharoplasty
achieves good cosmetic and functional results in patients with
dermatochalasis.4

Other surgical techniques have been suggested as treatment
for BEB. Selective peripheral facial nerve avulsion showed
high recurrence rate and risk of facial nerve palsy.9 Orbicularis
muscle resection (orbicularis stripping) was more effective. It
involves resecting muscles for eyelid closure (the orbicularis,
procerus, and corrugator muscle), but recurrence may occur
owing to incomplete removal of all orbicularis oculi.8,10

Botulinum toxin therapy is most commonly used for
blepharospasm. Five type A formulations and one type B
formulation are commercially available.11 Various botulinum
toxin type A show similar safety and efficacy, but they are
not interchangeable. Botulinum toxin type B is approved by
US Food and Drug Administration for cervical dystonia only.

In addition, FL-41 tinted lenses were helpful for BEB. They are rose-tinted lens that can improve light sensitivity
and blepharospasm, and also reduce the mean blink rate.12
Nevertheless, there is little information regarding the use of
FL-41 tinted lenses for AEO.

In conclusion, frontalis suspension can be a treatment option
for patients with BEB with AEO, especially in those who
failed botulinum toxin therapy. In the presence of coexisting
dermatochalasis, frontalis suspension can be combined with
blepharoplasty with direct fixation of silicone rod onto the
tarsal plate.

Conflicts of interest

As an Editor of the Journal, HKLY was not involved in
the peer review process for this article. All authors have no
conflicts of interest to disclose.

Funding/support

This research received no specific grant from any funding
agency in the public, commercial, or not-for-profit sectors.

Ethics approval

The patient was treated in accordance with the Declaration of
Helsinki. Informed consent was obtained from the patient for
the operations and the publication of clinical photos.
